## Thief Orienteering Problem (ThOP)

ThOP<sup>1</sup> is a **multi-component optimization problem**, it combines the **Orienteering Problem (OP)** and **Knapsack Problem (KP)**.

---

<sup>1</sup>André G. Santos et al. “The Thief Orienteering Problem: Formulation and Heuristic Approaches”. In: *2018 IEEE Congress on Evolutionary Computation (CEC)*. 2018, pp. 1–9

# Problem description

## Orienteering problem (OP)

OP is a **routing problem** in which the goal is to determine a path through a given set of points of interest that **maximizes a total score** while **satisfying a given time budget**.

# Problem description

## Orienteering problem (OP)

OP is a **routing problem** in which the goal is to determine a path through a given set of points of interest that **maximizes a total score** while **satisfying a given time budget**.

## Knapsack problem (KP)

KP is an **optimization problem** in which the goal is to **select a subset of items** from a given set such that **the total value** of the selected items **is maximized**, while the **total weight** of the selected items does **not exceed a given capacity**.

## ThOP Benchmark Overview

The ThOP benchmark is a collection of 432 instances. Each instance has unique characteristics, including:

- Number of cities: 51, 107, 280, or 1000.
- Number of items per city: 01, 03, 05, or 10.
- Knapsack types: uncorrelated (unc), uncorrelated with similar weights (usw), or bounded and strongly correlated (bsc).
- Knapsack size: 01, 05, or 10 times the size of the smallest knapsack.
- Maximum travel time: 50%, 75%, or 100%.

# Max-min ant colony optimization for ThOP

ACO++

## ACO++ overview

- ACO++, or Max-min Ant Colony Optimization for ThOP, emerged as the state-of-the-art algorithm upon its introduction by its authors.
- ACO++ algorithm is a combination of a heuristic approach based on MAX-MIN Ant Colony Optimization with a randomized packing heuristic and local searches.
- ACO++ outperformed all other previous algorithms (ACO, BRKGA, ILS, GA) by more than 96% of the total of test cases.

- 6 Conclusion

# ACO++'s Randomized Packing Heuristic

## Randomized Packing Heuristic

- 1 Consider the next item having the highest score.
- 2 If picking the item does not violate any constraints, add it to the packing plan.
- 3 While items are not all considered, go to step 1.

# ACO++'s Randomized Packing Heuristic

## Randomized Packing Heuristic

- 1 Consider the next item having the highest score.
- 2 If picking the item does not violate any constraints, add it to the packing plan.
- 3 While items are not all considered, go to step 1.

Item score  $s_i$  is determined using the formula

$$s_i = \frac{p_i^\theta}{w_i^\delta * d_i^\gamma}$$

# ACO++'s Randomized Packing Heuristic

## Randomized Packing Heuristic

- 1 Consider the next item having the highest score.
- 2 If picking the item does not violate any constraints, add it to the packing plan.
- 3 While items are not all considered, go to step 1.

Item score  $s_i$  is determined using the formula

$$s_i = \frac{p_i^\theta}{w_i^\delta * d_i^\gamma}$$

## Parameters

- $p_i$ : Profit of item  $i$ .
- $w_i$ : Weight of item  $i$ .
- $d_i$ : Distance from item  $i$ 's city to the ending city along the route.
- $\theta, \delta, \gamma$ : Randomized values within the range  $[0,1]$ .

# Investigating ACO++ Sensitivity to Parameters

## The extensive tuning process

- The ACO++ requires an extensive tuning process to achieve its out-performance results.
- The results were obtained using different sets of parameter values that have been extensively fine-tuned for each specific instance group.

## Experiment on ACO++ parameter sensitivity

Our experiments were carried out on two instance groups from the ThOP benchmark:

- a280\_01\_unc: 280 cities, 1 item per city, profits uncorrelated with weights.
- dsj1000\_01\_unc: 1000 cities, 1 item per city, profits uncorrelated with weights.

# Investigating ACO++ Sensitivity to Parameters

## Experiment 1

Used fine-tuned parameter sets for each instance group.

## Experiment 2

Swapped parameter sets between instance groups.

## Experiment 3

Increased  $\alpha$ ,  $\beta$ , and  $\rho$  by 3% and packing tries by 1.

## Experiment 4

Used average parameter values from 48 configurations.

**Hình:** Mean errors of results of 4 ACO++ experiments with different parameter sets on 18 instances belonging to 2 ThOP instance groups.

## Overview

- Our proposed method SAAS, stands for **S**elf-**A**daptive **A**nt **S**ystem, is an extension of ACO++.
- It can adapt its parameters based on the ThOP instance and the search process.
- It also has a lower time complexity in the route-finding and pheromone evaporation phases.

## Introduction

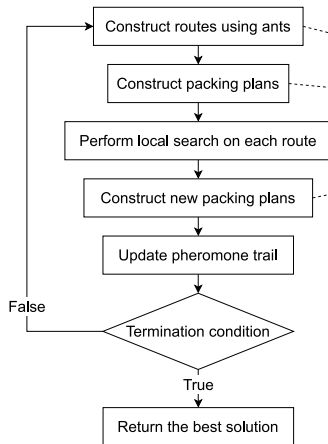

CMA-ES<sup>5</sup> stands for **Covariance Matrix Adaptation Evolution Strategy**, which is a **stochastic, derivative-free** method for numerical optimization of **non-linear** or **non-convex continuous** optimization problems.

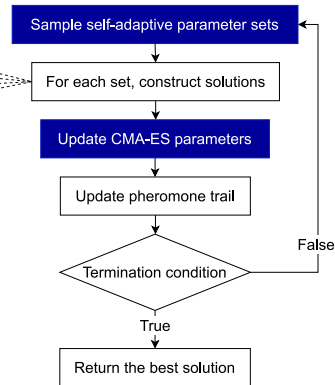

Hình: Simplified CMA-ES.

# Utilizing the profit diversity information for adaptation

# Utilizing the profit diversity information for adaptation

## Key ideas

Inspired by AACO-NC<sup>6</sup>, we use profit diversity information to dynamically change both the number of ants for each ES individual and the pheromone evaporation rate.

## Profit diversity information

$$p_i = \frac{\text{\#occurrences}(P_i)}{n_{\text{ants}}} \quad (1)$$

$S = \{P \mid P \text{ is a unique profit value found by the current swarm}\},$

$$H = - \sum_{i=1}^{|S|} p_i \cdot \log_2 p_i \quad (2)$$

<sup>6</sup>Petr Stodola et al. “Adaptive Ant Colony Optimization with node clustering applied to the Travelling Salesman Problem”. In: *Swarm and Evolutionary Computation* 70 (2022), p. 101056. ISSN: 2210-6502

# Utilizing the profit diversity information for adaptation

## Adapting the pheromone evaporation rate

- The evaporation rate **increases** for **high** profit diversity and **decreases** for **low** diversity.

$$\rho = \rho_{\min} + (\rho_{\max} - \rho_{\min}) \cdot \frac{H - H_{\min}}{H_{\max} - H_{\min}}. \quad (3)$$

## Adapting the number of ants for each ES individual

- Unlike the evaporation rate, the value of  $n_{\text{indv}}$  **increases** for **low** profit diversity to encourage exploration and **decreases** for **high** diversity to facilitate exploitation.

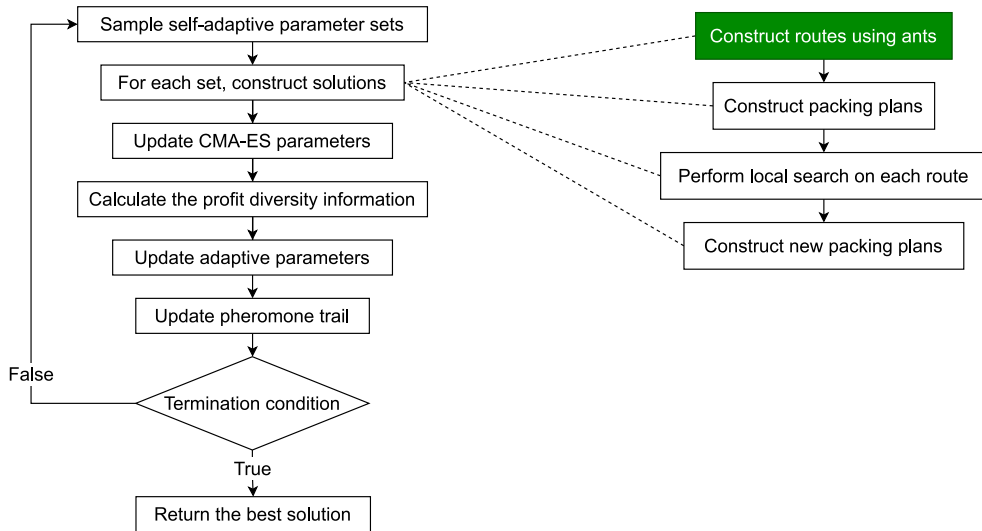

$$n_{\text{indv}} = n_{\text{indv\_max}} - (n_{\text{indv\_max}} - n_{\text{indv\_min}}) \cdot \frac{H - H_{\min}}{H_{\max} - H_{\min}}. \quad (4)$$

**Bảng:** List of Parameters controlled by Parameter Control Mechanisms

Parameter	Parameter control mechanism	Range
$\alpha$	Self-adaptive	[0, 1]
$\beta$	Self-adaptive	[0, 1]
$\rho_{\min}, \rho_{\max}$	Self-adaptive	[0, 1]
$\theta$	Self-adaptive	[0, 1]
$\delta$	Self-adaptive	[0, 1]
$\gamma$	Self-adaptive	[0, 1]
$n_{\text{indv}}$	Adaptive	$[n_{\text{indv\_max}}, n_{\text{indv\_min}}]$
$\rho$	Adaptive	$[\rho_{\min}, \rho_{\max}]$

# Ant traversal on cluster trees

# Ant traversal on cluster trees

## Key ideas

- We use hierarchical clustering to build the tree architecture.
- Each city has its own cluster tree that represents the edges going to  $n$  cities.
- Ants will traverse cluster trees instead of moving directly from one city to another.
- This way, we can reduce the time complexity of choosing the next city to  $\Theta(\log n)$ .

# Lazy evaporation

## Key ideas

- The key idea of lazy evaporation is to keep track of historical and desired states.
- The desired state consists of the number of times that pheromones need evaporating.
- Each edge has its historical state including the number of times that the pheromone of the edge has been evaporated.
- By comparing historical states and the desired state, we can determine how to calculate the desired pheromones of edges when needed.

# Experiments

## Hardware

Experiments were run on the same machine with Intel(R) Core(TM) i7-8750H @ 2.20GHz for a fair comparison.

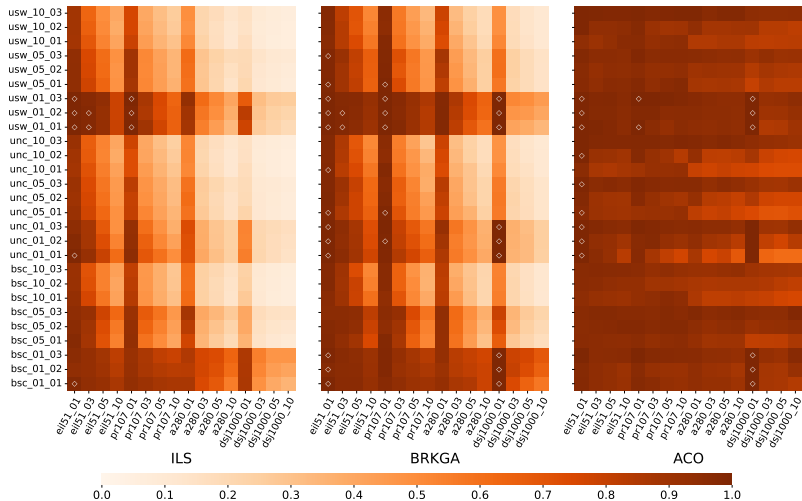

## Hyperparameter tuning

- BRKGA, ACO, and ACO++ used the same parameters fine-tuned in the ACO++ paper.
- 240,000 experiments were performed for tuning each algorithm. ILS had no parameters to fine-tune.
- evosax<sup>7</sup> framework was used to tune SAAS hyperparameters.
- 45,000 experiments were performed to tune SAAS for all benchmark instances.

- 6 Conclusion**

## Conclusion

- Parameter control mechanisms are incorporated to improve adaptability and flexibility.
- Lazy evaporation technique is used to reduce the time complexity of the evaporation phase.
- Hierarchical clustering is used to improve the time complexity of finding routes.
- SAAS is more efficient than ACO++ and requires only one hyperparameter set to run all 432 benchmark instances.
- The SAAS algorithm showcases remarkable performance when it surpasses all other algorithms for ThOP.
